A simplified method for determination of the rate of ethoxyresorufin-O-deethylase (EROD) activity in the urine, plasma, and erythrocytes of human subjects has been developed. This assay is based on our prior observation that human erythrocytes can catalyze the conversion of resorufin to its fluorescence product resorufin-7-oate. The amount of this product is a direct measure of the catalytic activity of the erythrocyte EROD. The reaction is linear with respect to time for 30 min. In this assay, the levels of product formed are proportional to the amounts of endogenous benzopyrene-DNA adducts present in the samples. However, the degree of enzyme specificity is lower than that of the "classical" ethoxyresorufin-O-deethylase assay. We have applied this method to the measurement of EROD activity in blood and urine samples from humans and compared these results with similar measurements made with the classical assay. The relative rates of EROD activity in the blood and urine are similar in the normal population. However, when measured with the present assay, the EROD activity in the blood and urine of smokers is lower than that in nonsmokers. Similarly, when measured with the present assay, EROD activity in the erythrocytes of patients with
